DATE OF RELEASE: JULY 4, 1969 – ATLANTA, GEORGIA 30333

EPIDEMIOLOGIC NOTES AND REPORTS HUMAN PLAGUE - New Mexico

The presumptive case of plague reported last week in an 18-year-old man in Placitas, New Mexico. (MMWR, Vol. 18, No. 25) has been confirmed. Identification of the isolate was confirmed by staining techniques, culture, mouse inoculation, fluorescent antibody examination, and bacteriophage lysis.

The patient made a complete recovery and was discharged from the hospital on June 26. No subsequent cases have been reported.

Field material gathered during the investigation is still being examined. To date, evidence of plague has been found in two field rodents. One was collected 100 yd. from the patient's residence, and the other about 4 miles away.

EPIDEMIOLOGIC NOTES AND REPORTS IMPORTED MEASLES CASES — Washington, D.C.

The first cases of measles reported in the District of Columbia since April 1968 occurred during May 1969 in two sisters, aged 21 months and 5 years. These cases were diagnosed at the Walter Reed Army Hospital clinic and were the first measles cases seen there in nearly 3 years.

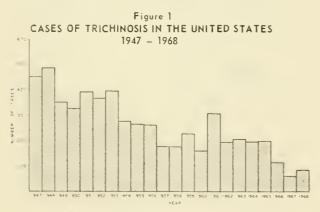

Both sisters had visited their grandmother in Smithfield, Johnston County, North Carolina, from early April through mid-May, While there they had contact with a young child with diagnosed rubeola. They returned to their home in Washington, D.C. on May 18. On May 20 the younger child and on May 22 the older girl developed an illness characterized by fever, conjunctivitis, cough, and a maculopapular rash. The older child was seen early in her illness. Scarlet fever was considered, but a throat

culture was negative for streptococci. Both children were seen several days later; one was then noted to have Koplik spots and the other a rash compatible with measles. Although both children had been followed regularly in a well-baby clinic, neither had received measles immunization because of frequent colds and febrile illnesses which had interfered with their immunization schedules. The children were kept at home during their measles illnesses, and no secondary cases were found in the neighborhood or among known contacts.

(Reported by William Long, M.D., Chief, Epidemiology Division, D.C. Department of Public Health; Lillian Ziegler, M.D., Civilian Physician, Pediatric Clinic, Walter Reed Army Hospital; and an EIS Officer.)

SURVEILLANCE SUMMARY TRICHINOSIS - United States 1968

In the United States during 1968, a total of 84 cases of trichinosis were reported, an increase over the 67 cases reported in 1967 (Figure 1). There were five outbreaks with four or more cases, and the first trichinosis-related death since 1966. The 84 cases were reported from 22 states (Table 1), New York reported the largest number of cases with 17, of which 12 were from New York City,

Of the \$4 cases, age was known for 74; the mean age was 32 years for men and 34 years for women. The sex of patients was reported in 78 cases; 41 were men and 37 women. The mean incubation period for the 50 cases with the date of consumption reported was 12 days. The mean period between date of onset and serologic diagnosis for 35 cases was 26 days. Sera were collected from 57 of the \$4 cases and 51 of these 57 cases were serologically positive. Muscle biopsy was performed in 28 cases, of which 21 were positive (Table 2).

Of the 84 cases, 60 were associated with pork products as the source of infection: 30 of these were related to sausage. Seven cases were associated with hamburger,

probably reflecting contamination of beef when ground in meat grinders used previously to grind pork. Eight cases were attributed to bear meat and two cases to wild swine.

The place where the meat was consumed was reported for 69 cases with 63 acquiring infection in homes and six in commercial eating places. The source of meat was determined in 57 cases; 43 purchased the meat from commercial sources, four acquired infection from farm grown and processed pork, and 10 cases were from wild game processed at home. Of the 84 cases, 36 claimed that the

INTERNATIONAL NOTES SMALLPOX

Smallpox incidence continues to decline throughout the 19-country area of the West and Central African Regional Smallpox Eradication and Measles Control Program, with only 14 cases reported during May 1969 (Figure 2).

Through the first 22 weeks (week ending May 31), 348 cases of smallpox were reported to the World Health Organization by the 19 countries (Table 3). This is a decrease of 90.1 percent from the 3,527 cases reported during the comparable period in 1968.

Since the beginning of the Program in January 1967, approximately 85 million smallpox vaccinations have been administered in the area, which has a 1969 mid-year population estimate of 119 million persons.

(Reported by Smallpox Eradication Program, NCDC.)
